

Yesterday 12:17 PM

So I'm going to build from the other chat, the most recent chat we just talked about. What do you remember from that?

Yeah. The most recent conversation was essentially about “**picking a character**” as a **deliberate way of being**, rather than pretending to be someone else.

The core model we were building was:

- **Character isn't just personality or beliefs.** It's a configuration of behavior, attention, posture, standards, reactions, social presence, etc.
- You can **observe an environment**, figure out what kind of person actually functions well within it, and then construct/inhabit that configuration.
- The interesting part is that it doesn't necessarily remain artificial. A “character” you deliberately inhabit can become **genuine** through repeated enactment.
- We were treating this almost like an engineering problem: **what does the successful agent look like, and what underlying way of being produces that outward behavior?**
- And you connected this to relationships. You said the same thought applies to **intimate relationships**: there is a particular *way of being* that makes an intimate relationship work, just as there is a way of being that works in other environments.
- You made an important distinction between **intimate relationships and marriage**. You don't think you're likely to get married, but the underlying model still applies to intimacy.

And I think the deeper thing you were getting at was that this isn't really about “**choosing a character**” in the theatrical sense.

It's more like:

What kind of person do I need to be in order for this particular form of life to actually work?

Then you can study the demands of that form of life, identify the corresponding character, and deliberately develop it.

That was where the conversation had gotten when you said, essentially, **“it is the same thought.”**

Awesome, awesome. Okay, so what I decided to do was create a task, and it's gonna be a task that I'm gonna be building inside of for weeks, maybe even months, you know, possibly years. But this is the title of the task, because it came to me, and I just did a dump of everything, I believe, because I believe that this dump has all the meat and juice to, like, kickstart this stuff and, you know, start thinking about everything correctly. Yeah.

title: Need to think about planning school / jobs success (going out, building relationships, thought leadership,

Show more

Yes. This is **more than enough to kick off the task**. And I think the important thing is that your dump already contains the architecture of the project, even though it is still in raw form.

I'd frame what you just produced like this:

The task

Planning school / jobs success through deliberate character construction.

Not merely “how do I get a job?” or “how do I succeed at school?”

The actual question is:

What kind of person am I deliberately constructing, and how does that person operate across school, work, mastery, projects, relationships, thought leadership, and the broader social world?

And then there are several interlocking systems underneath that.

1. Character study / character construction

This is the **core system**, not an accessory.

You were unusually explicit about this:

Character studying gets calendar time.

You're rejecting the idea that this is some vague self-development activity you do when you happen to feel like it.

You're treating it more like studying a technical discipline:

observe → **model** → **study** → **construct** → **test in circumstances** → **observe results** → **refine**.

And importantly, you're not designing a "work character."

You're studying a **whole person**.

Different environments:

- school
- workplace
- leadership
- friendship
- intimate relationships
- social environments
- intellectual environments
- entrepreneurial environments
- adversity
- success
- unfamiliar environments

The objective is a **stable underlying character** whose expression can appropriately vary by environment without becoming a different person.

That's a major distinction.

2. Mastery

You've separated mastery from projects.

That's important.

Your model isn't:

Build projects → put them on GitHub → get job.

It's closer to:

Choose a domain → understand what excellence actually consists of → deliberately become excellent at its underlying primitives.

You've already used this logic elsewhere:

- sales
- automation
- AI building
- physical skills
- parkour
- even things like cold showers

The principle is:

If I decide this is one of my things, I get good at it.

So mastery becomes the substantive asset.

Projects, credentials, GitHub, articles, etc. are **evidence / outputs / interfaces with the external world**.

They matter, but they aren't the thing itself.

3. Role selection

This is one of the biggest discoveries in the dump:

You don't yet have a rigorous model for choosing the role.

And therefore, before committing to a particular technical career path, you want to build the model for answering:

What role should I become?

Not based on today's job postings.

Not "what AI job is hot in September 2026?"

Instead:

What organizational function is structurally valuable?

You want to reason from:

- what companies actually need
- how organizations are structured
- what different people are responsible for
- what problems exist between functions
- what a startup needs versus a large organization
- what the first/second/third technical hire looks like
- what becomes necessary as an organization scales
- what underlying capabilities survive changes in technology

Then choose your position within that landscape.

That's much more robust than picking a job title.

4. The company as the unit of analysis

This may actually become one of the strongest methods in the whole task.

Instead of starting:

“Which job should I get?”

Start with:

“**Imagine the organization.**”

Then reconstruct it.

Company → functions → problems → people → responsibilities → interfaces → capabilities.

For example:

Why does this company need this person?

What problem are they solving?

Who works alongside them?

Who precedes them?

Who comes after them?

What does the organization look like before this role exists?

What changes after the role exists?

What does this person actually spend their day doing?

What capabilities make someone unusually good at this role?

And then eventually:

Do I actually want to be this person?

That's the bridge between **labor-market analysis** and **character construction**.

You're not merely selecting an occupation.

You're selecting a **mode of operating in an organization**.

5. Projects / credentials / external evidence

You also made a useful distinction here.

You don't need to panic about producing endless projects immediately.

You already have substantial evidence of activity through your existing work/building/writing.

So projects should increasingly become:

the place where mastery gets instantiated.

Rather than:

"I need a project because I need something for my résumé."

That creates a much better relationship between the components:

Mastery → projects → evidence → credentials → employment.

Instead of trying to manufacture credentials independently of actual competence.

6. Relationships / going out / social architecture

This is where the previous conversation about “**picking a character**” becomes much bigger.

You're not treating relationships as a separate self-help category.

You're asking:

Who am I socially?

How does this person:

- meet people?
- build relationships?
- maintain relationships?
- create communities?
- organize people?
- become useful to people?
- become trusted?
- introduce people to one another?
- create collective activity?
- participate in other people's projects?
- lead?
- follow?
- collaborate?
- pursue intimacy?

And this is where **Omcoda** potentially becomes interesting.

Not necessarily as “the company I need to make successful.”

But potentially as an **expression of the kind of social/organizational character you're interested in becoming.**

You could discover that the character you're constructing naturally creates organizations, networks, collectives, projects, communities, etc.

Then Omcoda becomes one possible **vehicle through which that character expresses itself.**

That's much deeper than “how do I fit my startup into my career plan?”

And then there is the meta-layer

I think this is the most important sentence in your dump:

Implementation becomes more about execution and less about “am I doing the right thing?”

That's the payoff you're actually chasing.

Because right now, a huge amount of cognitive load can come from simultaneously asking:

What should I do?

Who should I become?

Is this the correct career?

Is this the correct social strategy?

Am I wasting time?

Should I be building instead?

Should I be studying?

Should I be meeting people?

Should I be getting credentials?

The architecture you're proposing moves those questions **upstream**.

You spend serious time determining:

What is the structure?

Then you execute inside it.

And the structure itself remains revisable.

So it's not rigidity.

It's:

think deeply → construct architecture → execute → observe → iterate architecture.

Not:

think → act → doubt → change direction → think → act → doubt.

That's why you described it as potentially **easeful rather than easy**.

The work doesn't disappear.

But the work gets organized.

And I would **not** turn this dump into a polished master plan yet.

That would actually violate the spirit of what you're doing.

This is the **seed document**.

For weeks or months, you can keep throwing things into this task:

- observations
- career models
- characters
- people worth studying
- organizational structures
- social experiments
- school observations
- job descriptions
- technical domains
- relationship observations
- failures
- things that feel unnatural
- things that work
- things you discover about yourself
- things you discover about companies
- possible curricula
- possible roles
- possible projects

Then periodically we can **distill the accumulated material into the architecture**.

The eventual system could become something like:

Character

↓

Way of operating

↓

Role

↓

Mastery curriculum

Projects / evidence / credentials

Organizations / career

Relationships / social world

Life structure

And then the whole thing is continuously tested against reality.

That's a genuinely substantial project. The raw dump already gives us enough conceptual material to start working on it without prematurely deciding what the final answer is.

Okay, next step I need to do. So, the good thing is that my calendar and schedule change per semester, right? But anyway, let's— let me add some ticket points to this project, right? So there's the character, you know, let's just call it character development, all the way to a point where I need no more than two hours a week to, you know, let's call it refine or revise or iterate on the character itself. So where I'm not acting, but I'm actually watching and making improvements on paper, on my desk, call it that, right? Screenwriting, call it that. Let's say it would take roughly 25 hours of deliberate work at my desk to get it to a point

Show more

Yes. You just made a pretty important compression.

You took what initially looked like **20 separate life-planning problems** and discovered that a lot of them are actually **downstream of two upstream design problems**.

The two upstream systems

1. Character development

~25 hours initial deliberate work → establish the character architecture.

Then:

≤2 hours/week → observe, revise, refine, update.

That system determines things like:

- how you operate socially
- how you go out
- how you build relationships
- how you behave at school
- how you behave at work
- leadership style
- standards
- habits of engagement
- what kinds of environments you seek
- how you respond to different situations

And crucially, you're **not counting the actual living of the character** as part of those 2 hours. Those are the *desk/screenwriting hours* where you study and revise the model.

2. Role / career architecture

~25 hours initial deliberate work → determine the role architecture.

Then:

~8 hours/month → maintain and revise it.

And this isn't merely "pick a job title."

It contains:

- organizational analysis
- role selection
- organizational function
- what companies need
- what problems the role solves
- what capabilities matter
- mastery requirements

- learning curriculum
- sequence of mastery
- credentials
- project requirements
- evidence requirements
- likely organizations/environments
- how Omcode fits
- how your school program supports it

So you're right: **a huge amount of the “what should I actually do?” problem disappears once this architecture exists.**

Then there's a third layer you just identified

Execution planning.

Once the character and role architectures exist, you don't have to repeatedly reinvent your life.

You periodically ask:

Given the architecture, what actually needs to happen this month?

That produces things like:

- events to attend
- people/relationships to pursue
- extracurriculars
- school activities
- projects
- study blocks
- applications
- networking
- Omcode activities
- mastery work

And the **planning overhead** could genuinely be quite small relative to the execution itself.

Your rough estimate:

~8 hours/month

is therefore conceptually different from the 25-hour deep-design blocks.

So I'd currently model your system as:

Layer	Initial build	Maintenance
Character architecture	~25h	≤2h/week
Role/career architecture	~25h	~8h/month
Monthly execution planning	—	perhaps ~8h/month
Actual execution	ongoing	ongoing

And there's an important distinction:

The 25 + 25 hours aren't “learning everything.”

They're **figuring out what needs to be learned and why.**

That's why they're so powerful.

You don't need 25 hours to become a master technologist.

You need 25 hours to construct a sufficiently good answer to:

What am I trying to become, why, what does excellence in that role actually consist of, and what path will I use to get there?

Then you spend the next several years actually becoming it.

What I think you haven't explicitly separated yet

There's one major thing I'd add:

World / opportunity architecture

Not quite character. Not quite role.

It's:

Where does this character + role actually get deployed?

That includes:

- which companies
- which cities/environments
- which industries

- which communities
- which events
- which institutions
- which people
- which networks
- which opportunities
- which environments are worth entering
- which environments aren't worth your time

Some of this is generated by the role architecture, but I think it deserves to remain visible as its own downstream layer.

Because:

Role: "I am becoming X."

Character: "This is how I operate."

World: "These are the environments where that person should actually exist."

Then execution planning becomes almost mechanical:

Given who I'm becoming, what role I'm mastering, and what world I want to operate in, what should I put on the calendar this month?

That's the compression you're discovering.

And there's another beautiful consequence:

Your semester schedule can change without destroying the system.

That's exactly what you pointed out at the beginning.

The **architecture remains relatively stable**.

The calendar is the implementation layer.

Fall semester can have one implementation. Winter another. Summer another. A full-time job another. A different city another.

You don't rebuild yourself every semester.

You update:

Architecture → constraints → calendar.

That's a much cleaner system than trying to make one permanent schedule for your entire life.

I think this is the point where your “task” is starting to become less like a giant checklist and more like an actual **life operating system design project**.

ChatGPT can make mistakes. Check important info.
